On the fit and forecasting performance of New-Keynesian models

Marco Del Negro (FRBAtlanta), Frank Schorfheide (UPenn), Frank Smets (ECB) and Raf Wouters (NBB)

Model Evaluation in Macroeconomics
6 May 2005
Motivation

- DSGE models are not only attractive from a theoretical perspective, but are also emerging as useful tools for forecasting and quantitative analysis;
- Smets and Wouters (SW, 2003, 2005) find that estimated DSGE models a la Christiano et al (JPE, 2005) can compete with Bayesian VARs in terms of the marginal data density.
- This paper revisits some of the evidence on the “good” fit and forecasting performance of New Keynesian DSGE models, using the tools developed in Del Negro and Schorfheide (DS, 2003) for two main reasons.
Motivation (1)

• Sims (2003) criticizes the SW model comparison exercise (based on Bayes factors and posterior odds) on the basis of the argument that the models considered are too sparse.

• In such cases, posterior odds may lead to extreme outcomes and may also be highly dependent on the prior distribution. Sims (2003) proposes to “fill the space of models” to make the model comparison more robust.

• The DSGE-VAR methodology proposed in DS (2003) is one way of doing so.
DS (2004)

Unrestricted VAR

\[ Y_t = D(L)Y_{t-1} + u_t \]

Finite-Order VAR

DSGE-VAR(\(\lambda\))

\[ Y_t = D^\theta (L)Y_{t-1} + u_t \]

Restricted Finite-Order VAR

\( \lambda = 0 \)

\( \lambda = \infty \)

\( \lambda \)

Linearized DSGE

\[ X_t = A(\theta)X_{t-1} + B\varepsilon_t \]

\[ Y_t = C(\theta)X_t + \nu_t \]

VARMA in Y

Good approximation?
Motivation (1)

• In DS (2004), tightly specified DSGE models are used to form a prior for estimating highly parameterised VAR models. The hyper parameter ($\lambda$) captures the weight put on the prior. DS (2003) finds that putting a significant weight on the DSGE prior improves the forecasting performance of the VAR.

• In this paper, the hyper parameter ($\lambda$) is interpreted as a factor that scales the inverse of a prior covariance matrix of parameters that capture deviations from the DSGE model restrictions.
  - $\lambda=\infty$ implies that the prior on the misspecification parameters concentrates the mass around zero; DSGE model restrictions on the VAR parameters are dogmatically imposed.
  - $\lambda=0$ implies that the prior is flat; no DSGE restrictions imposed.
Motivation (1)

- By considering an entire range of hyperparameter values between the extremes (of the DSGE-VAR and an unrestricted VAR), one allows for varying degrees of deviations from the DSGE model restrictions and the assessment of misspecification becomes more refined and more robust.
Motivation (2)

• An analysis of the estimated stochastic processes in the work of Smets and Wouters indicates the presence of some misspecification:
  – These processes are often estimated to be very persistent and sometime exhibit a clear trend (in spite of being assumed stationary);
  – This is likely to also affect the estimates of the structural parameters (e.g. degree of wage and price stickiness).
• The DSGE-VAR methodology of DS (2003) allows us to relax some of the DSGE restrictions and investigate the effects on the structural model.
Benefits of the methodology

• The hyperparameter that has the highest posterior probability ($\lambda^\wedge$) can be interpreted as providing an assessment of the degree of misspecification.

• The DSGE-VAR($\lambda^\wedge$) provides a natural benchmark for comparing the empirical fit of the DSGE model (Schorfheide, 2001):
  – Out-of-sample forecasting performance
  – Parameter estimates
  – Impulse response functions (identification of VAR)

• This benchmark can be used to analyse the sources of misspecification in the DSGE model
Main findings

- The stationary state-space representation of the DSGE model is well approximated by a VAR with 4 lags, provided the error-correction terms are included;
- The posterior distribution of the hyperparameter $\lambda$ has an inverse U-shape, indicating that the fit of the autoregressive system can be improved by relaxing the DSGE restrictions. But the DSGE restrictions should not be ignored either.
- This finding is confirmed by out-of-sample forecasting exercises.
Main findings

• Regarding the nature of misspecification of the DSGE model, there are three main findings:
  – There is a shift towards less stickiness in prices and wages, less persistence in the shocks and less habit formation, when misspecification is allowed for;
  – Nevertheless, many the impulse responses in the optimal DSGE-VAR show an increased degree of persistence in particular in response to a government spending and labour supply shock;
  – The real effects of monetary policy are estimated to be larger and more persistent.
Outline of presentation

• Brief overview of the DSGE model:
  – variant of CEE (JPE, 2005) and SW (2003)
• Brief overview of the methodology:
  – similar to Del Negro and Schorfheide (2003), but different interpretation.
• Presentation of main findings;
• Conclusions and future work
The New Keynesian DSGE model

• Model is a variant of Altig et al (2002), Christiano et al (JPE, 2005) and SW (2003);

• Households consume, supply labor, enjoy money, set wages, accumulate capital subject to adjustment costs, choose capital utilisation and have access to a full set of state-contingent assets.
DSGE Model

Households’ Problem

Households maximize:

$$E_t \sum_{s=0}^{\infty} \beta^s b_{t+s} \left[ \log(C_{t+s}(j) - hC_{t+s-1}(j)) - \frac{\varphi_{t+s}}{1 + \nu_l} L_{t+s}(j)^{1+\nu_l} + \frac{\chi}{1 - \nu_m} \left( \frac{M_{t+s}(j)}{Z_{t+s}P_{t+s}} \right)^{1-\nu_m} \right]$$

subject to:

$$P_{t+s}C_{t+s}(j) + P_{t+s}I_{t+s}(j) + B_{t+s}(j) + M_{t+s}(j) \leq R_{t+s}B_{t+s-1}(j) + M_{t+s-1}(j) + A_{t+s}(j)$$

$$+ \Pi_{t+s} + W_{t+s}(j)L_{t+s}(j) + (R_{t+s}^k u_{t+s}(j)K_{t+s-1}(j) - P_{t+s}a(u_{t+s}(j))K_{t+s-1}(j)), $$

and

$$\bar{K}_t(j) = (1 - \delta)\bar{K}_{t-1}(j) + \mu_t \left( 1 - S \left( \frac{I_t(j)}{I_{t-1}(j)} \right) \right) I_t(j),$$

where firms use the “effective” capital: \( K_t(j) = u_t(j)\bar{K}_{t-1}(j). \)

The exogenous shocks \( \varphi_t, b_t, \) and \( \mu_t \) all follow AR(1) processes (in logs).
Households' Problem – Sticky Wages

Labor packers “pack” $L_t(j)$ labor into $L_t = \left[ \int_0^1 L_t(j) \frac{1}{1+\lambda_w} \, di \right]^{1+\lambda_w}$, and demand:

$$L_t(j) = \left( \frac{W_t(j)}{W_t} \right)^{-\frac{\lambda_w}{1+\lambda_w}} L_t,$$

where

$$W_t = \left[ \int_0^1 W_t(j)^{\frac{1}{\lambda_w}} \, di \right]^{\lambda_w}.$$

Households that can reset wages (probability $1 - \zeta_w$) solve:

$$\max_{\bar{W}_t(j)} \quad E_t \sum_{s=0}^{\infty} (\zeta_w \beta)^s b_{t+s} \left[ -\frac{\varphi_t + s}{\nu_t + 1} L_{t+s}(j)^{\nu_t + 1} \right]$$

s.t. budget constraint for $s = 0, \ldots, \infty$, demand for $L_{t+s}(j)$, and

$$W_{t+s}(j) = (\prod_{i=1}^{s} (\pi_* e^{\gamma})^{1-i_w}(\pi_{t+s-1} e^{\gamma+s-1} i_w) \bar{W}_t(j).$$
The New Keynesian DSGE model

- Intermediate goods producers use capital services and labor; set prices in a monopolistic competitive market and face a random walk productivity process;
- Final goods producers aggregate a continuum of intermediate goods.
Producers' Problem

\[
\max P_t(i)Y_t(i) - W_tL_t(i) - R_t^kK_t(i),
\]

subject to the technology:

\[
Y_t(i) = \max \{K_t(i)^\alpha(Z_tL_t(i))^{1-\alpha} - Z_tF, 0\},
\]

where \(z_t = \log(Z_t/Z_{t-1})\) follows the process:

\[
(z_t - \gamma) = \rho_z(z_{t-1} - \gamma) + \epsilon_{z,t}.
\]
Producers’ Problem – Sticky Prices

Final goods producers “pack” $Y_t(i)$ into a composite good:

$$Y_t = \left[ \int_0^1 Y_t(i)^{1+\lambda_{f,t}} \, di \right]^{1+\lambda_{f,t}}, \quad (\ln \lambda_{f,t} - \ln \lambda_f) = \rho_{\lambda_f}(\ln \lambda_{f,t-1} - \ln \lambda_f) + \sigma_{\lambda_f} \epsilon_{\lambda,t},$$

and demand:

$$Y_t(i) = \left( \frac{P_t(i)}{P_t} \right)^{-\frac{1+\lambda_{f,t}}{\lambda_{f,t}}} Y_t,$$

where

$$P_t = \left[ \int_0^1 P_t(i)^{\frac{1}{\lambda_{f,t}}} \, di \right]^{\lambda_{f,t}}.$$

Producers that can reset prices (probability $1 - \zeta_p$) solve:

$$\max_{P_t(i)} E_t \sum_{s=0}^{\infty} \zeta_p^s \beta^s \Xi_{t+s}^p \left( \hat{P}_t(i) \left( \prod_{l=1}^s \pi_{t+l-1}^{\tau_p} \pi_{t+s}^{1-\tau_p} \right) - MC_{t+s} \right) Y_{t+s}(i)$$

s.t. demand for $Y_{t+s}(i)$ and , $MC_{t+s} = (1 - \alpha)^{-(1-\alpha)} Z_{t+s}^{-(1-\alpha)} \alpha^{-\alpha} W_{t+s}^{1-\alpha} R_{t+s}^\alpha$. 
Government

\[ P_t G_t + R_{t-1} B_{t-1} + M_{t-1} = T_t + M_t + B_t \]

where \( G_t = (1 - 1/g_t)Y_t \) and:

\[ \ln g_t = (1 - \rho_g) \ln g + \rho_g \ln g_{t-1} + \sigma_g \varepsilon_{g,t}. \]

The central bank follows a nominal interest rate rule:

\[
\frac{R_t}{R^*} = \left( \frac{R_{t-1}}{R^*} \right)^{\rho_R} \left[ \left( \frac{\pi_t}{\pi_*} \right)^{\psi_1} \left( \frac{Y_t}{Y_*} \right)^{\psi_2} \right]^{1-\rho_R} \sigma_R e^{\varepsilon_{R,t}}
\]

where \( Y_t^* \) can be either the stochastic steady state level of output \( (Y_t^* = Y_t^s) \) or the level output that would have prevailed in absence of nominal rigidities \( (Y_t^* = Y_t^f) \).
Detrending and model solution

\[ c_t = \frac{C_t}{Z_t}, \quad y_t = \frac{Y_t}{Z_t}, \quad i_t = \frac{I_t}{Z_t}, \quad k_t = \frac{K_t}{Z_t}, \quad \bar{k}_t = \frac{\bar{K}_t}{Z_t}, \]

\[ r_t^k = \frac{R_t^k}{P_t}, \quad w_t = \frac{W_t}{P_t Z_t}, \quad m_t = \frac{M_t}{P_t Z_t}, \quad \bar{p}_t = \frac{\bar{P}_t}{P_t}, \quad \bar{w}_t = \frac{\bar{W}_t}{W_t}, \]

\[ \xi_t = \Xi_t Z^*_t, \quad \xi_t^k = \Xi_t^k Z_t, \]

Log-linearize + Sims’ gensys → transition equations.
Measurement equations

Output growth (log differences, quarter-to-quarter, in %):

\[ 100 \times ( \ln Y_t - \ln Y_{t-1} ) = 100 \times ( \tilde{y}_t - \tilde{y}_{t-1} + \tilde{z}_t ) + 100 \gamma \]

Consumption growth (\ldots):

\[ 100 \times ( \ln C_t - \ln C_{t-1} ) = 100 \times ( \tilde{c}_t - \tilde{c}_{t-1} + \tilde{z}_t ) + 100 \gamma . \]

Investment growth (\ldots):

\[ 100 \times ( \ln I_t - \ln I_{t-1} ) = 100 \times ( \tilde{\iota}_t - \tilde{\iota}_{t-1} + \tilde{z}_t ) + 100 \gamma . \]

Real wage growth (\ldots):

\[ 100 \times ( \ln W_t - \ln P_t - \ln W_{t-1} + \ln P_{t-1} ) = 100 \times ( \tilde{\omega}_t - \tilde{\omega}_{t-1} + \tilde{z}_t ) + 1 \]

Hours worked (log):

\[ \ln L_t = \tilde{L}_t + \ln L^* + \ln L^{adj} \]

Inflation (quarter-to-quarter, in %):

\[ 100 \times ( \ln P_t - \ln P_{t-1} ) = 100 \tilde{\pi}_t + 100 \ln \pi^* . \]

Nominal interest rate (annualized, in %):

\[ 400 \times ( \ln R_t ) = 4 \times 100 \tilde{R}_t + 400 \times \ln R^* . \]
The DSGE-VAR methodology

- VAR/VECM representation of the DSGE model
- Prior distribution of the VAR parameters given the DSGE parameters
- Posterior distribution of VAR parameters and DSGE parameters
- Identification
VAR/VECM representation

- We approximate DSGE model by VAR

  \[ \Delta y_t = \Phi_0 + \Phi_1 \Delta y_{t-1} + \ldots + \Phi_p \Delta y_{t-p} + u_t, \quad E[u_t u_t'] = \Sigma \]  

  (1)

- or alternatively by a VECM

  \[ \Delta y_t = \Phi_0 + \Phi_{\beta}(\beta'y_{t-1}) + \Phi_1 \Delta y_{t-1} + \ldots + \Phi_p \Delta y_{t-p} + u_t. \]  

  (2)

- \( Y \) is \( T \times n \) matrix with rows \( \Delta y'_t \); \( X \) is \( T \times k \) matrix with rows \( x'_t = [1, \Delta y'_{t-1}, \ldots, \Delta y'_{t-p}] \);

  \( U \) is \( T \times n \) matrix with rows \( u'_t \), and \( \Phi = [\Phi_0, \Phi_1, \ldots, \Phi_p]' \).

- Write VAR as

  \[ Y = X \Phi + U; \]  

  (3)

  VECM looks similar
Three steps to derive posterior

• Calculate prior distribution of VAR parameters given the structural DSGE parameters
• Calculate posterior distribution of VAR parameters given the structural DSGE parameters
• Calculate posterior distribution of VAR parameters and structural DSGE parameters
Step 1

- Log-lIn DSGE model has in general no exact finite-order VAR representation, but can often be well approximated with few lags, provided $y_t$ is covariance stationary.

- Define autocovariance matrices

\[
\Gamma_{XX}(\theta) = E^D_\theta[x_t x'_t], \quad \Gamma_{XY}(\theta) = E^D_\theta[x_t y'_t]
\]

$E^D_\theta[\cdot]$ expectation under DSGE model.

- Let

\[
\Phi^*(\theta) = \Gamma^{-1}_{XX}(\theta) \Gamma_{XY}(\theta).
\]

(4)

and

\[
\Sigma^*(\theta) = \Gamma_{YY}(\theta) - \Gamma_{YX}(\theta) \Gamma^{-1}_{XX}(\theta) \Gamma_{XY}(\theta).
\]

(5)

- Note that $E^{VAR}_{\psi^*(\theta), \Sigma^*(\theta)}[x_t x'_t] = E^D_\theta[x_t x'_t] = \Gamma_{XX}(\theta)$. 

Prior distribution of VAR parameters

\[ \Sigma_u | \theta \sim \mathcal{IW} \left( \lambda T \Sigma_u^*(\theta), \lambda T - k, n \right) \quad (40) \]

\[ \Phi | \Sigma_u, \theta \sim \mathcal{N} \left( \Phi^*(\theta), \frac{1}{\lambda T} \left[ \Sigma_u^{-1} \otimes \Gamma_{XX}(\theta) \right]^{-1} \right), \quad (41) \]

where \( \mathcal{IW} \) denotes the inverted Wishart distribution. The latter induces a distribution for the discrepancy \( \Sigma_u^\Delta = \Sigma_u - \Sigma_u^* \).
Step 2: Posterior distribution of VAR parameters

It is straightforward to show, e.g., Zellner (1971), that the posterior distribution of $\Phi$ and $\Sigma$ is also of the Inverted Wishart – Normal form:

$$
\Sigma_u|Y, \theta \sim IW\left((\lambda + 1)T \hat{\Sigma}_{u,b}(\theta), (1 + \lambda)T - k, n \right)
$$

(43)

$$
\Phi|Y, \Sigma_u, \theta \sim N\left(\hat{\Phi}_b(\theta), \Sigma_u \otimes (\lambda T \Gamma_{XX}(\theta) + X'X)^{-1}\right)
$$

(44)

where $\hat{\Phi}_b(\theta)$ and $\hat{\Sigma}_{u,b}(\theta)$ are the given by

$$
\hat{\Phi}_b(\theta) = (\lambda T \Gamma_{XX}(\theta) + X'X)^{-1}(\lambda T \Gamma_{XY} + X'Y)
$$

(45)

$$
= \left(\frac{\lambda}{1 + \lambda} \Gamma_{XX}(\theta) + \frac{1}{1 + \lambda} \frac{X'X}{T}\right)^{-1}\left(\frac{\lambda}{1 + \lambda} \Gamma_{XY} + \frac{1}{1 + \lambda} \frac{X'Y}{T}\right)
$$

$$
\hat{\Sigma}_{u,b}(\theta) = \frac{1}{(\lambda + 1)T} \left[(\lambda T \Gamma_{YY}(\theta) + Y'Y) - (\lambda T \Gamma_{YX}(\theta) + Y'X) \times (\lambda T \Gamma_{XX}(\theta) + X'X)^{-1}(\lambda T \Gamma_{XY}(\theta) + X'Y)\right].
$$

(46)
Step 3: Implementation

- Place prior over $\theta$.
- MCMC methods to generate draws from the joint posterior of $\theta$, $\Phi$, and $\Sigma$.
- Use marginal data density to form a posterior for $\lambda$:

$$p_{\lambda}(Y) = \int p(Y | \theta, \Sigma, \Phi)p_{\lambda}(\theta, \Sigma, \Phi)d(\theta, \Sigma, \Phi).$$

(10)
Identification

- To assess the DSGE model based on impulse response comparisons between DSGE and VAR/VECM we need a mapping from VAR innovations into structural shocks.

- An (exactly) identified VAR is a triplet: \((\Phi, \Sigma, \Omega)\), where \(\Omega\) is orthonormal:
  \[
  \left( \frac{\partial y_t}{\partial \epsilon_t'} \right)_{VAR} = \Sigma_{tr} \Omega.
  \]

- The DSGE model is identified: there is a matrix \(\Omega^*(\theta)\) that maps the variance-covariance matrix of innovations into the portion attributed to each shock:
  \[
  \left( \frac{\partial y_t}{\partial \epsilon_t'} \right)_{DSGE} = \Sigma^*_{tr}(\theta) \Omega^*(\theta).
  \]

- Identification of DSGE-VAR (for each draw of \(\Phi, \Sigma, \theta\)): \((\Phi, \Sigma, \Omega^*(\theta))\)
Findings

Can DSGE-VAR reproduce the dynamics of the DSGE model when
\[ \lambda \to \infty? \ - \ Dealing \ with \ Cointegration \]

- \( Y, C, I, \) and \( W \) all grow along a balanced growth path – according to the DSGE model.

- A standard VAR in growth rates (even for \( \lambda \to \infty \)) does not impose these cointegrating restrictions.

- If we introduce an error correction term into the VAR (we call it VECM):

\[ \beta' y_{t-1} = \begin{bmatrix} \ln C_t - \ln Y_t \\ \ln I_t - \ln Y_t \\ \ln(W_t/P_t) - \ln Y_t \end{bmatrix}. \]

we can reproduce the dynamics of the DSGE model with only a few autoregressive lags.
How Well Do DSGE-VAR/VECM Approximate the DSGE Model?
Preliminary: Direct evaluation of the DSGE model

• Choosing the DSGE specification;
• In-sample fit of the DSGE model;
• Parameters of the DSGE model;
• Exogenous processes.

Conclusions

• Application of the DSGE-VAR tool kit to a relatively rich New Keynesian DSGE model suggests that some model features are still at odds with the data:
  – Relaxing the DSGE model restrictions improves the fit in terms of Bayesian marginal likelihood and out-of-sample forecasting performance of the DSGE-VAR.
  – In particular, the co-trending implications of the DSGE model are not fully born out by the data;
  – When this misspecification is not taken into account, the structural parameter estimates are biased towards more persistence (more persistent shocks, higher habit formation and higher degree of nominal frictions)
Work ahead

• Work harder on building models that can be successfully taken to non-detrended data to fulfil Kydland and Prescott (1982)’s original promise of integrating growth and business cycle theory;
• Need to develop approaches that use the DSGE model restrictions, but down-weight those frequencies where the DSGE’s model implications are more at odds with the data.
• Monetary policy analysis with misspecified models (Del Negro and Schorfheide, 2004);
